Purpose The concept of designing or modifying home environments plays an important role in maintaining safety for older adults (65 and older). Poor staircase architectural design could contribute to increasing the risk of falling for older adults. The purpose of this research is to evaluate staircase architectural design by investigating the risk of falling associated with staircase elements and aiming to improve the surrounding environment for older adults living independently in their homes. This paper presents research which is built around the following hypotheses: ‘Improving the architectural design of staircase could reduce the risk of falling for older adults’. Method This research provides an integrated evidence-based assessment that combines all aspects related to staircase architectural design, represented in the following 3 stages. Stage 1 constructs a hierarchy of four elements which represent the architectural design of the staircase as follows: (i) staircase geometrical design; (ii) handrail design; (iii) lighting; and (iv) step design. Each element is divided to a number of features; for instance, handrail design, if exists, is divided into five features: (i) handrail height; (ii) handrail cross-section; (iii) handrail surface texture; (iv) handrail extension; and (v) minimum handrail-wall clearance. Each feature is divided into a number of scenarios representing the different architectural design alternatives for that feature: e.g., variation on handrail heights. A rating factor that represents the degree by which the proposed scenario reduces the risk of falling for older adult, is assigned to each scenario. Stage 2 develops a rating system for the analyzing staircase elements and features which present the degree to which each element and its features reduce the risk of falling for older adults. In this stage, a mathematical model is developed to calculate the rating value for different staircase design scenarios. Stage 3 develops a decision tree analysis module called a design assessment tree (DAT) which represents a complete vision for different staircase design scenarios. A case study is presented in order to illustrate the effectiveness of the proposed methodology. Results & Discussion The result of the developed rating system is a rating number for different staircase design scenarios that represent the degree by which the proposed staircase architectural design reduces the risk of falling for older adults. Figure 1 illustrates the optimal design scenario for the geometrical design element, which is part of the developed DAT for the staircase assessment procedure. DAT works as a manual for architects to represent the staircase assessment for any proposed design, and to visualize the optimal design scenario comparing to other scenarios in the each branch.

Keywords: staircase design, older adult, risk of falling

INTRODUCTION

Ascending and descending staircases have been reported as a difficult daily activity for older adults1. Statistically, one out of four older adults is expected to fall when climbing staircases in the home environment2. Falling for older adults might lead to injuries3. In addition to experiencing physical harm, older adults might experience loss of confidence or develop a fear of falling, which will impact their performance while ascending or descending staircases4,6,7. There is a wide variation of staircase configurations such as spiral staircases, straight staircases with landing, and U-shaped staircases. Each staircase configuration has been associated with different handrailings, lighting and step dimensions (riser and tread). The concept of modifying staircase configuration plays an important role in maintaining safety for older adults. Previous studies have investigated the cause of falling through ascending or descending staircases for older adults1,2,6,7. Other studies have recommended staircase modifications for handrail, lighting and step design to reduce the risk of falling4,10,16.

This paper presents an evidence-based integrated framework that combines all aspects related to staircase architectural design to reduce the risk of falls in older people. A practical case study of staircase design is presented from the perspective of reducing the risk of falling for older adults to demonstrate the effectiveness of the proposed methodology. First, the staircase is divided into a number of elements that represent its architectural design . Then; those elements are divided into a number of features that provide more detailed specifications. Each feature has different scenarios that represent the architectural design alternatives for that feature. A rating factor is calculated for each element and its associated features to represent how much it reduces the
risk of falling for older adults based on previous evidence-based studies. The proposed methodology assesses the staircase design, while not the actual value or true meaning of the rating numbers presented. Design Assessment Tree (DAT) has been developed to represent a complete vision of different staircase design scenarios. DAT could work as a manual for architects to represent the staircase assessment for any proposed design, and to visualize the optimal design scenario compared to other scenarios in each branch.

STAIRCASE ELEMENTS AND FEATURES
The staircase is divided into four design elements: staircase geometrical design, handrail design, lighting, and step design elements. This categorization follows the logical divisions provided in the building code. Handrail, lighting and step specifications are provided in the building code as subdivisions of the staircase design specifications. In addition, staircase geometric design is considered to be a design element that presents the formation of the staircase as an independent design object, which can only be tracked by the geometrical design of the staircase. The staircase geometrical design element is divided into the staircase configuration and the number of steps per flight, represented as two subdivision features. Each element is divided into a number of features that define its architectural design, as illustrated in Figure 1.

Fig. 1. A flow chart for staircase elements and features

PROPOSED RATING SYSTEM
The developed rating system represents the degree by which the risk of falling for older adults is reduced. A rating factor (R) is assigned to different alternatives (scenarios). This rating factor is calculated based on an evidence-based comparison with alternative scenarios.

To set the comparison, a scale of numbers between 0.00 and 1.00 has been adopted to indicate how much each scenario may reduce the risk of falling for older adults. The rating factor 1.00 represents optimal risk reduction; the scaled numbers from 1.00 to 0.00 represent the scaled reduction of the risk of falling for older adults, as illustrated in Table 1. The rating factor 0.0 means that the feature does not exist. For example, if the handrail does not exist, the rating factor of the “handrail existing” feature will be 0.00.

Table 1. Explanations of rating factors

<table>

ELEMENT 1: STAIRCASE GEOMETRICAL DESIGN
From the perspective of investigating the risk of falling for older adults, staircase configuration10, 13, 17-19, and length of each flight12, 13, 18 of the staircase are two important factors. Therefore, staircase geometrical design, as an element, can be divided into two main features that specify its architectural design: 1) staircase configuration which represents variation in staircase shapes (straight, circular or composite); and 2) number of steps per flight.

Feature 1: staircase configuration
This paper covers a wide range of staircase configurations including: 1) U-shape staircases; 2) Quarter turn staircases; 3) Straight staircases with landing; 4) Straight staircases without landing; 5) Helical staircases; 6) Spiral staircases; and 7) Composite staircases, illustrated in Figure 2, arranged from highest to lowest risk reduction in terms of falling for older adults. The optimal staircase design has been found
to be the U-shaped staircase design\textsuperscript{16,20}, which has an associated rating factor of 1.00.

The composite staircase is defined as a mixed staircase configuration in one staircase connecting two floors. The worst staircase configuration is the composite staircase, as it causes an irregular gait pattern which increases the risk of falling for older adults\textsuperscript{10,18,19,21}. The composite staircase has an associated rating factor of 0.20. The remaining staircase configurations have a range of rating factors according to how much each staircase configuration reduces the risk of falling for older adults.

**Feature 2: number of steps per flight**

Long flights (over 12 steps) or short flights (less than 6 steps) have been found to increase the risk of falling\textsuperscript{12,13,18}. There are four scenarios for the “number of steps per flight” feature: 1) \(10 \leq \text{number of steps per flight} < 10\), which is the optimal case and has an associated rating factor of 1.00; 2) \(7 \leq \text{number of steps per flight} < 10\); and 3) \(\text{number of steps per flight} \geq 12\) which has the worst case scenarios with an associated rating factor of 0.25 indicating that they highly increase the risk of falling for older adults.

**Element 2: Handrail Design**

The handrail is an essential tool that assists older adults’ movement while ascending and descending staircases\textsuperscript{22}. Handrail design consists of six features: handrail existence, handrail height, handrail cross-section, handrail surface texture, handrail extension, and minimum handrail-wall clearance. These six features are chosen to represent the handrail design specifications that have been found to reduce the risk of falling for older adults. To express importance of each scenario compared to others, a suitable rating factor is assigned to each of the scenarios according to the potential reduction in the risk of falling for older adults.

**Feature 1: Handrail Existence**

Evidence suggests that as a person ages, the need for a handrail increases. Safety in ascending and descending a staircase is further enhanced when a handrail exists on both sides of the staircase\textsuperscript{11,22}. The scenarios for “handrail existence” are: 1) to have one handrail on each side of the staircase, which is the optimal design scenario with a rating factor of 1.00; 2) to have one handrail on one side of the staircase, which has an associated rating factor of 0.7 as a moderate case; and 3) to have no handrail on either side of the staircase with a rating factor of 0.00 as the feature does not exist.

**Feature 2: Handrail Height**

Handrail height is the vertical line from the top of the rail to the outside edge of the staircase, as illustrated in Figure 3(a). There are four scenarios for the “handrail height” feature\textsuperscript{15,18}: 1) \(910 \leq \text{handrail height} \leq 970\), which is considered the optimal handrail height, as it is the most preferred height by older adult users\textsuperscript{15}, and has an associated rating factor of 1.00; 2) \(910 \leq \text{handrail height} \leq 970\); and 3) \(\text{handrail height} \geq 1,000\), both of these cases are the worst case scenarios with a rating factor of 0.4 as lower than moderate design; and 4) \(970 \text{ handrail height} \leq 1,000\), which is neither the optimal nor the worst case with an associated rating factor of 0.7 as an over moderate design.
Thus have a rating of 0.8, which is the worst scenario as it has been found that a short handrail extension increases the risk of falling more than no handrail extension. 11, thus the associated rating factor is 0.4.

Feature 6: minimum handrail-wall clearance

The purpose of investigating the minimum handrail-wall clearance, illustrated in Figure 3(b), is to provide a sufficient space to grasp the handrail in case of a falling emergency. There are four scenarios for the “minimum handrail-wall clearance” feature: 1) a smooth wall surface and handrail-wall clearance ≥ 57-mm; and 2) a rough wall surface and handrail-wall clearance ≥ 75-mm, both of these cases are the optimal cases which have a rating factor of 1.00; 3) a smooth wall surface and handrail-wall clearance < 57-mm; and 4) a rough wall surface and handrail-wall clearance < 75-mm, these two cases are the worst scenarios as they increase the risk of having finger injuries while moving the hand on the handrail and increase the risk of falling when ascending or descending the staircase. 11, and thus have a rating factor of 0.4 indicating a lower than moderate design.

Element 3: Lighting

Poor vision is associated with increasing the risk of falling for older adults on staircases as they often require an increased lighting level. 24, 25. The lighting element is divided into three features that specify: 1) illumination level; 2) consistency of lighting; 3) light switch types and locations.

Feature 1: Illumination level

Lighting for older adults has been recommended by Illuminating Engineering Society of North America-IESNA to be a minimum of 300-lux throughout the entire staircase. 24. The “Illumination level” feature is divided into two scenarios: 1) illumination level 300-lux, which is the optimal scenario and has an associated rating factor of 1.00; and 2) illumination level ≤ 300-lux, which is the worst scenario and has an associated rating factor of 0.4.

Feature 2: Consistency of lighting

Providing consistent lighting throughout the entire staircase is a very important factor that contributes to reducing the risk of falling for older adults. 18, 24. Providing inconsistent lighting may cause shaded areas on staircases which could cause confusion and might result in falls. 18, 24. Two scenarios are provided for the “consistency of lighting” feature: 1) consistent staircase lighting, which is the optimal scenario and has an associated rating factor of 1.00; 2) inconsistent staircase lighting, which is the worst
Feature 3: light switch types and locations
In order to reduce the risk of falling, light switches need to be placed away from the staircase path and should be two-way \(^{18, 19}\). Four scenarios are provided for the “light switches” feature. The first scenario is light switch away from staircase path and two-way light switch, which is the optimal case and has an associated rating factor of 1.00. The second and third scenarios are: 1) light switch through staircase path and two-way light switch, and 2) light switch away from staircase path and one-way light switch, both scenarios are slightly over the moderate case with associated rating factor of 0.6. The last scenario is light switch through staircase path and one-way light switch, which is the worst case with an associated rating factor of 0.4.

ELEMENT 4: STEP DESIGN
The step design element considers step design specifications, which are: 1) going depth; riser height; nosing shape and dimensions; and step finishing material (see Figure 4). In this paper, the selected step design specification is based on the most preferred step dimensions provided in previous evidence-based studies for different age groups, including older adults\(^{16, 18}\).

Feature 1: going depth
The going depth represents the depth of the tread without nosing (see Figure 4). For the “minimum going depth dimension” feature, there are three scenarios\(^{16, 18}\): 1) \(280 \leq \text{going depth} \leq 330\), which is the optimal scenario and has an associated rating factor of 1.00; 2) \(\text{going depth} < 280\); and 3) \(\text{going depth} \geq 330\). The latter two scenarios are the worst case and have an associated rating factor of 0.4.

Feature 2: riser height
Three scenarios are provided for the “minimum riser height dimension” feature\(^{16, 18}\): 1) \(15\text{\/mm} \leq \text{riser height} \leq 190\) which is the optimal scenario and has an associated rating factor of 1.00; 2) riser height \(\leq 152\); and 3) riser height dimension \(\geq 190\). The latter two scenarios are the worst case and have an associated rating factor of 0.4.

Feature 3: nosing
Safer staircase design can be achieved by optimizing the staircase nosing\(^{18, 26}\). The optimal scenario for the “nosing design” feature is to be rounded with nosing depth between 15-mm and 25-mm\(^{18, 26}\). The worst case scenario is not to be rounded with nosing depth outside of the range of the optimal scenario. The worst case has an associated rating factor of 0.25 as it is highly associated with increasing the risk of falling for older adults\(^{26}\). Intermediate cases such as satisfying the optimal nosing dimension, but not satisfying the optimal shape also have intermediate rating factors.

Feature 4: step finishing material
Finishing step material represents the texture, pattern and color of the finishing material of each staircase step. The optimal case scenario for the “finishing step material” feature is to have cohesive finishing material with uniform slip-resistance for the staircase steps\(^{18, 26}\), which has an associated rating factor of 1.00. The worst case scenario is to have non-cohesive finishing material and non-uniform slip-resistance for staircase steps. In this case, the associated rating factor is assigned to be 0.4.

ASSESSMENT CALCULATIONS
One scenario is selected to represent the proposed staircase design. Based on the rating factor (R) that is assigned to each scenario for each feature, an average rating factor \(\bar{R}(Y)\) is calculated for each element, representing the selected scenario of each feature. This average rating factor represents how much the proposed features for each element reduces the risk of falling for older adults. The average rating factor must satisfy Equation 1.

\[
\bar{R}(Y) = \frac{\sum R(X)}{n}
\]

Where:
- \(\bar{R}(Y)\) = average rating factor (\(\bar{R}\)) for element Y;
- \(R(X)\) = rating factor (R) for feature X;
- \(Y\) = index for element symbol;
- \(X\) = index for feature symbol; and
- \(n\) = the total number of features for element Y (n=2 for staircase geometrical design (G), n=6 for handrail design element (H), n=3 for lighting element (L), and n=4 for step design element (S)).
A rating number (N) is generated to represent and rank the importance of each of the four elements. The summation of the four rating numbers is 100. This paper proposes an equal rating number (N) for the four staircase elements (25 each). The corrected rating number Nc(Y), is calculated by multiplying the rating number by the average rating factor of each element, which represents how much each element, relative to the other elements, reduces the risk of falling for older adults. The corrected rating number Nc(Y) for each of the four elements must satisfy Equation 2.

\[ N_c(Y) = \overline{R}(Y)N(Y) \]  \hspace{1cm} (2)

Where:

- \( N_c(Y) \) = corrected rating number for element Y;
- \( \overline{R}(Y) \) = average rating factor (\( \overline{R} \)) for element Y;
- \( N(Y) \) = rating number (N) for design element Y;
- \( Y \) = index for element symbol.

The summation of the four corrected rating numbers represents how much the proposed staircase design reduces the risk of falling for older adults. Thus, in the perfect hypothetical case, the staircase rating must equal 100. The total rating for staircase design is calculated satisfying Equation 3.

\[ N_{total} = \sum N_c(X) \]  \hspace{1cm} (3)

Where:

- \( N_{total} \) = total rating number of the proposed staircase architectural design;
- \( Nc(X) \) = corrected rating number for staircase element (X).

A scale is developed to categorize the total rating of the staircase from the perspective of reducing the risk of falling for older adults. A total rating from (100 to 90) represents the optimal staircase design; (90 to 65) represents strong staircase design; (65 to 40) represents moderate staircase design; (40 to 15) represents a weak staircase design; and (15 to 0) represents the staircase design associated with the highest risk of falling.

**DESIGN ASSESSMENT TREE (DAT)**

The Design Assessment Tree (DAT) is a decision tree that has only decision nodes. DAT works as a manual for architects to represent a complete vision for staircase assessment for any proposed design. In addition, DAT allows the architect to visualize the optimal design scenario compared to other scenarios in each branch. Each individual branch in the DAT carries the rating factor (R) of each scenario. There are two columns at the end of each DAT branch, as illustrated in Figure 5: the first column lists the average rating factor for each design scenario, calculated by satisfying Equation 1; the second column displays the corrected rating number Nc(Y) for each design scenario, calculated by satisfying Equation 2. DAT is developed for each element independently.

**CASE EXAMPLE**

To illustrate the effectiveness of the proposed staircase assessment, the case example of straight staircase without landing is presented, as shown in Figure 6. The proposed staircase consists of 16 steps per flight, with a handrail height of 900-mm and it exists in one side of the staircase. The handrail cross-section shape is rectangular with smoothed edges. The illumination level = 250-lux and the lighting throughout the staircase is consistent. The light switch is away from the staircase path and is a two-way switch. Tables 2, 3, 4 and 5 illustrate the actual scenarios for each feature based on the proposed staircase design, and provide the associated rating factors.

</tbody>
</table>

The corrected rating number for the staircase geometrical design element (G), handrail design (H), lighting (L), and step design (S) is calculated satisfying Equation 2 as follows:

- \( N_G = R(G) N(G) = 0.325 \times 25 = 8.13 \)
- \( N_H = R(H) N(H) = 0.72 \times 25 = 18 \)
- \( N_L = R(L) N(L) = 0.8 \times 25 = 20 \)
- \( N_S = R(S) N(S) = 0.725 \times 25 = 18.13 \)

The total rating for the proposed straight staircase without landing is obtained by satisfying Equation 3. The total rating for the proposed staircase design (64.26) indicates that the proposed straight staircase without landing has a moderate staircase design.

- \( N_{total} = 8.13 + 18 + 20 + 18.13 = 64.26 \)

The same results can be obtained by selecting DAT branches that express the proposed scenarios. The total rating of the staircase can be optimized by selecting better scenarios for different design features from the developed DAT. For example, as illustrated in Figure 6, the number of steps per flight can be optimized by selecting the optimal scenario, with an associated rating factor of 1.00, which is to have between 10 to 12 steps per flight. Also, the effect of choosing a certain scenario on the average rating factor ( ) can be tracked. Therefore, the architect might decide to add a landing in the middle of the staircase to satisfy the optimal number of steps per flight; in that case, the average rating factor will be optimized from 0.33 to 0.7. This process can be applied to different features of the four elements to optimize the whole staircase design. The advantage of using DAT for optimization is that rating factor for the different scenarios of each feature are visually easier to extract and compare.

The average rating factor ( ) for the staircase geometrical design element (G), handrail design (H), lighting (L) and step design (S) is calculated satisfying Equation 1 as follows:

- \( R(G) = (0.4 + 0.25) / 2 = 0.325 \)
- \( R(H) = (0.7 + 0.4 + 0.7 + 1 + 0.5 + 1) / 6 = 0.72 \)
- \( R(L) = (0.4 + 1 + 1) / 3 = 0.8 \)
- \( R(S) = (0.4 + 1 + 0.5 + 1) / 4 = 0.725 \)

![Fig. 6. scenarios for number of steps per flight and its associated rating factors](image_url)
CONCLUSION
This paper proposes an integrated assessment for staircase architectural design which aims to reduce the risk of falling for older adults. The assessment considers all the features of staircase design that could be improved through different scenarios. The assessment has been developed by evidence-based analysis of the staircase elements (staircase geometrical design, handrail design, lighting, step design). The proposed integrated staircase rating system enables architects to assess the proposed staircase design with the aim of reducing the risk of falling for older adults. Additionally, the developed integrated staircase rating system and DAT can be used as a design tool to improve staircase design through choosing alternative scenarios for different design features. A case example is analyzed to demonstrate the use of the proposed staircase assessment.
