ABSTRACT: The study proposed a maintenance rating program (MRP) in Taiwan which combines the methods of DEcision MAKing Trial and Evaluation Laboratory (DEMATEL) and Analytic Network Process (ANP) to evaluate maintenance activities accurately. In the view of the provincial and county roads in Taiwan, DEMATEL was employed to compute the effects between criteria through experts' interviews and questionnaire surveys, and ANP was used to determine the weights of elements in each criterion. The results showed that the five key factors for the maintenance activity evaluations are road safety, road surface, road construction, road management, and facility and landscape of road. The proposed MRP based on the DEMATEL and ANP methods is more suitable than the traditional decision-making methods to solve problems with different degrees of effects among criteria which are used to the evaluations of maintenance activities.

1. INTRODUCTION

Field engineers are responsible for maintaining desired levels of service for various components in a road system such as roadway, roadside, and so on. These levels of service (LOS) is affected by a number of factors such as comfort, economics, safety, aesthetics and so on. Considering these complex factors, inconsistent decisions were made and resulted in unintended lower levels of maintenance activities [1]. This study develops a maintenance rating program (MRP) for the provincial and county roads in Taiwan by DEMATEL and ANP methods.

2. REVIEWS OF THE MAINTENANCE RATING PROGRAM (MRP)

The purpose of MRP is to provide information that should be used to schedule and prioritize routine maintenance activities. In Florida Department of Transportation (FDOT)'s MRP, each MRP criterion is comprised of multiple maintenance features and characteristics (elements) that represent specific maintainable items. [2]. In the Kentucky Transportation Cabinet (KYTC)'s MRP,

the LOS provided on interstates, national highway system, state primary and secondary, rural secondary for all maintenance features (elements) will not be the same [3].

3. THE DEMATEL AND ANP METHODS

The DEMATEL can confirm interdependence among criteria and construct the interrelations between criteria to build an IRM (impact-relation map) [4]. The ANP is the general form of the analytic hierarchy process (AHP) which has been used in multi-criteria decision making to release the restriction of hierarchical structure [5].

4. DEVELOPMENT OF MRP IN TAIWAN

This study attempts to develop one appropriate and feasible framework of MRP focusing on both provincial and county roads in Taiwan through the questionnaire interviews. Five criteria and totally twenty-three elements are as follows:

- C1 (Road safety): unsafety resulted from man-hole covers (E1), slipping resulted from traffic marking (E2), insufficient lighting (E3), and wrong placed traffic signs (E4).

- C2 (Road surface): potholes and depressions on pavements (E5), subgrade flowed away (E6), damaged man-hole covers (E7), uneven pavements (E8), drainage failure (E9), and damaged gutter cover (E10).
- C3 (Road construction): information related to constructions (E11), notice of construction duration (E12), deficient refilling (E13), and repeatedly construction (E14).
- C4 (Road management): reduced or narrow lanes (E15), invading right-of-way (E16), insufficient parking lots (E17), and heavy traffic volume (E18).
- C5 (Facility and landscape of road): sign and signal failure (E19), messy and dirty road (E20), untidy landscape of roadside (E21), improper streetlamp (E22), and landscape images (E23).

The DEMATEL method is used to detect complex relationships and build the IRM (Fig. 1) of relations among five criteria. The total-influence matrix is shown in Table 1. A value under 0.9 resulted in too complex. The ANP is employed to deal with the dependent five criteria to obtain the weights of criteria and elements. This study adopts the normalized matrix, which is obtained by the DEMATEL method, to transform the unweighted supermatrix (which ignores the different effects among criteria) to a weighted supermatrix in the ANP to overcome the problem of interdependence and feedback among five criteria. The weights for elements in each criterion are shown in Table 2.

5. CONCLUSIONS

This study developed a MRP focusing on the provincial and county roads based on the DEMATEL and ANP methods. The proposed MRP framework is more suitable than the traditional decision-making methods to solve problems with different degrees of effects among criteria. The proposed MRP has the highly potential to be practical to the maintenance activities evaluations in Taiwan.
