Abstract - Mechanized earthworks for post-disaster reconstruction largely forks into unmanned construction at hazardous working sites and manned one at less hazardous sites. In order to avoid secondary disasters, it is significant and required to compensate operator’s realistic sensation in order to enhance spatial awareness in the mechanized earthworks. The mechanized earthworks consist of a series of discrete works, which are sometimes independently and at other time interactively performed by different workers and managed by small and medium contractors. Generally, a variety of construction machines made by different manufactures are used there. On the other hand, diverse machine guidance systems come from different vendors. Most of them are self-contained and constitute an independent unit in and of itself. Here, are demanded inexpensive and easy-to-use software systems with sensors capable of easily mounting and demounting. The software systems of those should be not embedded in specific construction machines but available to multiple ones.

To overcoming problems like those, our primary efforts target on fabricating information modelling system for mechanized earthworks by utilizing open source software. The information modelling here means a process involving acquisition of field data and feedback of relevant digital representations of physical and functional characteristics of works in progress. This paper presents framework of field data acquisition and exploratory spatio-temporal visualizations, enhancement of spatial awareness, enhancement of communication, and conclusions with a discussion of the contributions included in this paper. Finally, some open problems are also pointed out.

1 Introduction

Motivations and objectives in this study, and structure of this paper are reported in this Section.

1.1 Compensation of Operator’s Realistic Sensations

Mechanized earthworks for post-disaster reconstruction largely forks into unmanned construction at hazardous working sites and manned one at less hazardous ones. When facing such dangerous situations, in order to avoid any secondary disasters, we demand unmanned operations.

Handling joysticks to operate construction machines, either directly or remotely, is an inherently eye-hand coordination task. The eye-hand coordination means to control eye movements with hand movements, and as processing visual representation of the situational views to handle joysticks along with the use of proprioception of the hands, or vice versa.

In case of manned operation at less hazardous working site for loading, hauling and dumping (LHD) of earth and rocks, operators would handle their machines based on their own realistic sensation given on the seat of their pants. For examples, distance and clearance perception based on front views, possible motion space, and velocity, acceleration, jerk, jolting, rattling, rolling, pitching, and yawing of the machine body.

In case of unmanned operation at hazardous working sites for removal of earth and rocks, operators can't feel their realistic sensation, and have to remotely operate their machines in a narrow field of view from camera-monitor system at the control station. Problems here include:

1. Machine operability,
2. Difficulty in a task at hand,
3. Performances limited by bearings of operators in
their behavioural frameworks, and
(4) Continuous/intermittent mental workload on them.
Therefore, it is significant and required to
compensate operator’s realistic sensation in order to
enhance spatial awareness, in other words, conscious
awareness of actions.

1.2 Enhancement of Communication

Mechanized earthworks consist of a series of
discrete works, e.g., digging, loading, hauling, dumping,
grading, embanking, compacting, etc., which are
sometimes independently and at other time interactively
performed by different workers and managed by small
and medium contractors. Generally, a variety of new
and used construction machines made by different
manufactures are utilized in the mechanized earthworks.

It is said that machine guidance systems will be able
to improve construction accuracy and productivity [1],
[2]. At present, diverse machine guidance systems come
from different vendors. Most of them are self-contained
and constitute an independent unit in and of itself.
Considering use of different construction machines, it is
difficult for workers to coordinate data among the
diverse machine guidance systems, and to generate
significant information based on the data as linking
them to the other systems. In addition, the up-front cost
of the machine guidance systems might be a huge
burden and a ball and chain to the small and medium
contractors in Japan. They would demand inexpensive
and easy-to-use software systems with devices, which
are capable of easily mounting and demounting on
different construction machines made by various
manufactures. The software systems of those should be
not embedded in specific construction machines but
available to multiple ones.

Therefore, it might be difficult for workers to grasp
current conditions of the each work related to one
another, and, not to mention, almost impossible for
them to know or reason the present and future situations
of the whole work process on a real time basis. Here, it
is very important to enhance communication as to work
process and operations between the people concerned.

1.3 Objectives

To overcoming the problems like these as described
above, our primary efforts target on fabricating an
information modelling system on mechanized
earthworks by utilizing open source software based on
GNU General Public License [3]. The information
modelling here means a process involving acquisition of
field data and feedback of relevant digital representations of physical and functional
characteristics of works in progress.

1.4 Structure of this Paper

This paper is organized as follows. First, we
introduce framework of field data acquisition and
exploratory spatio-temporal visualizations in Section 2.
Secondly, in Section 3, we report enhancement of
spatial awareness, put concretely, feedback of
quantitative indexes and exploratory spatio-temporal
visualizations of potential hazards in unmanned
construction. Thirdly, enhancement of communication
in the mechanized earthworks is given in Section 4. In
Section 5, we conclude with a discussion of the
contributions included in this paper. Finally, some open
problems are also pointed out.

2 Framework of Field Data Acquisition
and Information Feedback

Discrete spatio-temporal events are occurred in
space with time by construction work practices. Data
pertaining to the events are automatically collected in
real time by the inexpensive devices. These devices are
capable of easily mounting and demounting, which
consist of six-degree accelerometers, GPS receivers,
active tags, compact PCs, smart phones, etc., and
sometimes manually acquired by key-in as needed.

Figure 1 shows framework to acquire filed data and
feedback relevant digital representations of physical and
functional characteristics of works in progress.

Figure 1. Framework of filed data acquisition and
information feedback

Changes over time in spatio-temporal events are
classified as follows [4], [5]:
(1) Existential changes, i.e. appearance and
disappearance,
(2) Changes of spatial properties: location, shape
or/and size, orientation, altitude, height, gradient
and volume, and
(3) Changes of thematic properties expressed through
values of attributes: qualitative changes and changes of ordinal or numeric characteristic.

Exploratory spatio-temporal visualization of the above changes would be done by the open source software the R, which is a language and environment for statistical computing and graphics [4], [6] as focusing on:

(1) When and where, then what,
(2) When and what, then where, and
(3) Where and what, then when.

Figure 2 shows an image of the exploratory spatio-temporal visualization in this study. Numerical and graphic indicators here would be derived by:

(1) Detecting trends of consecutive increasing or decreasing values and change points latent in time series of the data, and
(2) Providing visual representation of work environments based on-demand processing of requests.

Figure 2. Image of the exploratory spatio-temporal visualization in this study

3 Enhancement of Spatial Awareness

In this Section, we present feedback of quantitative indexes and exploratory spatio-temporal visualization that will be able to enhance operator’s spatial awareness.

3.1 Feedback of Quantitative Indexes

The spatial awareness is very important for operators at their control room to infer and understand the present and future surroundings of their own construction machines or heavy-duty dump trucks and to watch themselves in the work space. In addition, it is significant and required to compensate operator’s realistic sensation, when remotely operating construction machine at dangerous spots, for example, at the steep slope, at the ridge of steep cliff, etc.

Figure 3 shows the information flow to assist operators. Construction machines have on-board devices that are composed of tools as follows:

(1) Tri-axial accelerometer,
(2) Tri-angular velocity meter,
(3) GPS receiver,
(4) Smart Phone or tablet PC, and
(5) Communication module.

These devices would be inexpensive and capable of mounting and demounting on any construction machine for earthworks.

Figure 3. Information flow to assist operators

Besides, are used wireless LAN-based devices that consist of active tags and the detection instruments with about 100 m effective range [7]. The each dump truck carries an active tag. The detection instruments are put in position on the side of the entrance to the loading and the dumping spots, respectively. The detection instruments successively receive signals from the active tags with the dump trucks that come into the effective cover range. Then the detection instruments automatically send the Web server system via the Internet the time stamps and the IDs of the active tags.

Based on field data given by the above on-board devices, are periodically and automatically generated and feedback quantitative indexes regarding operators’ bearings [8], the productivity [9], [10], and the physical cues [11].

Examples of the quantitative indexes as to operators’ bearing include:

(1) Mean cross rate,
(2) Magnitude of impact loads,
(3) Operability of orientation control,
(4) Learning capability,
(5) Difficulty in a task at a hand, and
(6) Response capability

Examples of the quantity indexes related to productivity include:

Concrete hauled

Compaction

Spatio-temporal events

Earthworks

Concrete hauled

Longitude

Time

Latitude

On-board Devices
Active tags and the detection instruments

Periodical feedback of quantitative indexes regarding evaluation of operators’ bearings

Real-time feedback of physical cues

Information Resources

Spatio-temporal visualization of requests
(1) Moving distance,
(2) Number of repositions, 
(3) Actual operation rate, and 
(4) Productivities of the LHD such as number of 
loading and dumping, distance hauled, work 
volume hauled, cycle time, etc.

Physical cues pertaining to posture of machine body 
and hazard factors latent in work places are feed back 
in real time. Examples of the physical cues include: 
(1) Posture of machine body such as inclination, 
rolling, pitching, 
(2) Positions of bucket pin, 
(3) Advance alert as to skidding, bumping, and rolling 
over, and 
(4) Advance proximity warning

To let operators recognize danger efficiently when 
remotely operating their machines, the numeric and 
graphic indicators with respect to the quantitative 
indexes would be intuitively context-sensitive assists to 
compensate operators’ realistic sensation.

Even under direct viewing, operators and the people 
concerned could not accurate at making inferences 
about the relative position of objects, the productivity 
of work in progress, and operators’ bearings. For securing 
safety, reliable and effective remote control, it becomes 
very important to provide operators with the 
information described in this Section.

3.2 Exploratory Spatio-temporal 
Visualization of Potential Hazards

Since operators could not easily envisage any hazard 
latent in unmanned earthwork process without any back 
ground information in a narrow field of view from 
camera-monitor system at the control station. It would 
be helpful and significant for operators in the control 
station to see severe dangerous spots with marks, and to 
watch the advance proximity warning on their monitors, 
when approaching to them.

Besides, exploratory spatio-temporal visualization of 
terrain and hazards are given with information resources 
such as digital elevation model and digital maps. 
Examples of the exploratory spatio-temporal 
visualization include: 
(1) Scatter plot, 
(2) Ground surface contour, 
(3) Heat map, 
(4) Slope and aspect, 
(5) Marginal plot of terrain, and 
(6) Hazard map

Figure 4 shows the ground surface contour of 
construction area ant the trajectory of the heavy-duty 
dump truck (blue points), which hauls no-slump 
concrete to construct a multilayer check dam against 
avanche of earth and rocks in Unzen-Fugendake. The 
multilayer check dam as shown in Figure 5 has been and 
is being constructed in severe hillside of which the 
gradients and aspects are shown in Table 1, and the 
gradients is visualized in Figure 6.

Figure 4. Ground surface contour and marginal plots 
of across each coordinate of construction area

Figure 5. Multilayer check dam has been and is being constructed

Figure 6. Visualization of gradients in construction area
Figure 7 displays hazards regarding crosswise skiddy spots (red bubbles) latent in the no slump concrete haulage roads (blue dots). Also, we could visualize the longitudinal skiddy spots and the bumpy spots. For want of space, the charts like those are left out in this paper. The hazards latent in haulage road are detected based on existence of trends such as consecutive increasing or decreasing values in time series of tri-axial acceleration responses with longitudinal and latitudinal coordinates.

Table 1. Gradient and aspect (unit: degree)

Hazardous spots like those might emerge at different places as the earthworks are progressing with time. To ensure safe and reliable haulage works, it is very significant to display the hazardous spots in advance on the monitor before starting and during work operations.

4 Enhancement of Communications

We have been and are developing the information modelling system, which enables the people concerned to share information on the no-slump concrete haulage and the compaction works in progress and to enhance communications among them. Figure 8 shows system configuration to enhance communications among the people concerned. This system enables them to peruse the analysis results, summary statistics and graphics of the works in progress anytime anywhere. Figure 9 shows a confirmation scene of compaction works in progress by the vibration roller in the outdoors other than at the control room.

4.1 Visualizations of No-slump Concrete Haulage Works

The no-slump concrete is hauled by 10 ton dump trucks from the ready-mixed concrete batching plant to the spot where it is transferred to heavy-duty dump trucks. Subsequently, the heavy-duty dump trucks
being remotely controlled haul the no-slump concrete to the designated dumping spot. In addition, a bulldozer spreads the no-slump concrete, and subsequently a vibration roller compacts [7].

Figure 10 shows the line chart of cumulative numbers both of arrivals of ton dump trucks to and the departures from the concrete batching plant for loading no-slump concretes.

Figure 10. Line chart of arrivals and departures of 10 ton dump trucks at concrete batching plant

Figure 11 shows the progress curve of the no-slump concrete haulage.

Figure 11. Progress curve of the no-slump concrete haulage

Besides, Figure 11 includes a base line for a comparison objective, which connects points of 0%, 33%, 66%, 100% at the time line axis and the corresponding 0%, 25%, 75%, 100% at the axis of the concrete volume hauled with a green line.

Figure 12 shows a spatio-temporal visualization of movements of a heavy-duty dump truck being remotely controlled to haul the no-slump concrete toward the designated dumping spot. Then the heavy-duty dump truck runs at an average of 18 kilometres an hour.

Figure 12. Movements of heavy-duty dump truck being remotely controlled

The people concerned can watch these Figures anytime, anywhere. It can be easily seen from these Figures that there are no queuing lengths at both of the ready-mixed concrete batching plant and the transhipment place to the heavy-duty dump tracks. In addition, there is nothing of accumulative delays in the movements of the heavy-duty dump trucks.

4.2 Visualizations of Compaction Works

Figure 13 shows an example of display of compaction works by the machine guidance system for the vibration roller at the control room. This machine guidance system is self-contained and constitute an independent unit in and of itself only for the operator at the control room. Therefore, the people except the operator can not watch the display somewhere other than at the control room.

In contrast, the information modelling system enables them to peruse analysis results, summary statics and exploratory spatio-temporal visualization of the compaction works in progress by the vibration roller anytime, anywhere.

Figure 14 shows the number of compactions in progress. The Information modelling system also provides data regarding work stating time, current time, work time elapsed, distance covered, and work finish.
time. Then the vibration roller walks at an average of 6.7 kilometres an hour.

Figure 13. Display of compaction works by machine guidance system at control room

Figure 14. Number of compactions in progress

Figure 15 shows the exploratory spatio-temporal visualization of the compaction works in progress. Furthermore, Figure 16 shows the progress curve of the compaction works.

The compaction works by the vibration roller are done intermittently. As reported in Section 4.1, the concrete haulage still reserves the capacity. So, it is possible to increase more the concrete placement areas in parallel. In contrast, earthworks volume per hour burden on a backhoe would be larger.

5 Conclusion and Some Open Problems

The information modelling presented in this paper means a process including:
(1) Automatically gathering field data,
(2) Feedback of physical cues as to machine behaviour,
(3) Showing exploratory spatio-temporal visualization of hazards latent in in-situ earthwork process, and
(4) Enhancement of communication regarding work process and operations.
And then the information modelling system enables workers to:
(1) Pick a set of building block of information at the right level of abstraction,
(2) Provide operators with the opportunities to reflect on their own bearings as facing their own works at hand,
(3) Reduce likely stress in remote control operations of machines, and
(4) Take timely and quickly correct actions based on detailed visibility of appearances and motions of the mobile entities in a whole unmanned construction process.

Taken together, the workers concerned could get in-depth insight into the work process while showing hints to improve safety and productivity with detailed reporting. Accordingly, it would be possible to secure traceability and accountability with the mechanized earthworks.

In future, remotely dexterous operations in close proximity to other would be required, when unmanned construction system would be deployed in various kinds of post-disaster recovery and reconstruction, for example, approaching to the target (e.g., inspection, repair, monitoring another one), positioning or repositioning dangerous materials, connecting an object with other, grasping and stacking sandbags or gabions, inserting nozzle into a fuel filler port for replenishment, and so on. For securing safety, reliable and effective operations, we will be not just focusing on the best way but the variety of better ways to provide operators with physical cues, which would enhance
(1) Awakening spatial awareness,
(2) Perception of distance and clearance,
(3) Recognition of possible motion space,
(4) Grasping posture of machine body, and
(5) Improvement of operator’s skill.
In addition, we will do further research and development on exploratory spatio-temporal visualization of:
(1) Earthworks by backhoe,
(2) Terrain being changed with earthwork operations, and
(3) Civil engineering structure under construction
